Abstract

The aim of this paper is to present a binomial model which will value different exotic options i.e. cash-or-nothing, asset-or-nothing and power options. In the first chapter we present our theoretical research. The second part of this paper presents a program we wrote on MS Excel which valuates the European exotic options.

Exotic Options With The Binomial Model

Introduction

The Binomial Model

The binomial model introduced by Cox, Ross and Rubinstein in 1979 is a very useful and popular technique for pricing an option\(^1\) for two reasons – its simplicity and flexibility. First, this approach uses simple calculus, without the need of the complicated mathematical theory of stochastic Brownian motions and second, it gives a fast and numerically accurate method to price American options.\(^2\)

The binomial option pricing formula is based on an assumption that the stock price follows a multiplicative binomial process over discrete periods. The rate of return of the stock over each period can have two possible values: \(u-1\) with the probability \(q\), or \(d-1\) (\(1-d\) as shown in J. C. Hull, 2005) with the probability \(1-q\).\(^3\) This can be represented with a following diagram:

![One period binomial model](image)

As shown in Graph 1 the binomial model is characterized by \(u\) and \(d\) which are constants describing the potential price increase or decrease during a time period. Following we present the Cox-Ross-Rubinstein formula for \(u\) and \(d\):

\[
u = e^{\sigma \sqrt{dt}}, \quad d = e^{-\sigma \sqrt{dt}}
\]

where \(dt\) is the time interval between observations of the price and \(\sigma\) the volatility.

---

Binary options

Binary options are options with discontinuous payoff. It is a type of option where the payout is either fixed after the underlying stock exceeds the predetermined threshold (or strike price) or is nothing at all.

The most common binary options are:

- Cash-or-nothing call
- Cash-or-nothing put
- Asset-or-nothing call
- Asset-or-nothing put

Binary Call Options pay either:

- a fixed cash settlement amount, if the underlying index settles at or above the strike price at expiration or
- nothing at all, if the underlying index settles below the strike price at expiration.

Binary Put Options pay either:

- a fixed cash settlement amount, if the underlying index settles below the strike price at expiration or
- nothing at all, if the underlying index settles at or above the strike price at expiration.

Valuing cash-or-nothing options

In a risk-neutral world, the probability of the asset price being above the strike price at the maturity of an option is $N(d_2)$. Therefore the value of cash-or-nothing call and put in the Black-Scholes is:

\[
\text{Call: } Q e^{-rT} N(d_2), \quad \text{Put: } Q e^{-rT} N(-d_2)
\]

where $Q$ is the fixed amount which is paid at the strike time $T$ and $r$ is the risk-free interest rate.

8. J. C. Hull, op. cit., p.535
Valuing asset-or-nothing-options

Analogously to the cash-or-nothing options we can value the asset-or-nothing options. They value is given by:

\[
\begin{align*}
\text{Call: } S_0 e^{-qt} N(d_1), & \quad \text{Put: } S_0 e^{-qt} N(-d_1)
\end{align*}
\]

where \( S \) is the initial stock price, \( q \) is the dividend rate.\(^9\)

Power options

Power options are a class of exotic options in which the payoff at expiry is related to the \( x \)th power of the stock price, where \( x \) is some power \( x > 0 \). For a power option on a stock with price \( S_t \) having strike price \( K \) and time to expiry \( T \), the payoff is \( \max(S_T^x - K, 0) \) for a call, and \( \max(K - S_T^x, 0) \) for a put. Within the Black–Scholes model, closed-form solutions exist for the price of power options.\(^10\) \(^11\)

Valuing power options

Notations:

- \( c \) – value of power call option
- \( p \) – value of a power put option
- \( x \) – power of stock price
- \( S \) – a stock with given price
- \( q \) – fixed dividend yield
- \( r \) – assumed fixed interest rate
- \( K \) – strike price
- \( T \) – time to expiry

---

\(^9\) J. C. Hull, op. cit., p. 536
\(^11\) http://demonstrations.wolfram.com/PricingPowerOptionsInTheBlackScholesModel/
The value of a power call option is given by:

\[ c = S^x e^{-\left( (x-1) \frac{r+\sigma^2}{2} - xq \right)T} N(d_1) - Ke^{-rT}N(d_2). \]

while the value of a put is:

\[ p = Ke^{-rT}N(-d_2) - S^x e^{-\left( (x-1) \frac{r+\sigma^2}{2} - xq \right)T} N(-d_1). \]

where

\[ d_1 = \frac{\ln \left( \frac{S}{K} \right) + (r - q + \frac{1}{2} \sigma^2)T}{\sigma \sqrt{T}} \quad \text{and} \quad d_2 = d_1 - x\sigma \sqrt{T} \]

\[ ^{12} \text{E. G. Haug, op. cit., p. 116} \]
Solution

To write our program we used VBA. It valuates the european cash-or-nothing and asset-or-nothing options and presents the result as a binomial tree.

The presented example shows the outcome for the figures shown in Table 1.

### Table 1 – Properties of the European cash-or-nothing option

<table>
<thead>

Table 3 – Binomial tree for the European cash-or-nothing option
Conclusion

In this paper we presented information about a binomial model which valuates cash-or-nothing and asset-or-nothing options. In the first part we have shown the theoretical research and presented information about the binomial model and binary options. In the second part of this paper we introduced a program written on MS Excel which valuates the European cash-or-nothing and asset-or-nothing options.
